Abstract

In this paper we investigate an extremal problem on binary phylogenetic trees. Given two such trees T_1 and T_2 , both with leaf-set $\{1, 2, \dots, n\}$, we are interested in the size of the largest subset $S \subseteq \{1, 2, \dots, n\}$ of leaves in a common subtree of T_1 and T_2 . We show that any two binary phylogenetic trees have a common subtree on $\Omega(\sqrt{\log n})$ leaves, thus improving on the previously known bound of $\Omega(\log \log n)$ due to M. Steel and L. Székely. To achieve this improved bound, we first consider two special cases of the problem: when one of the trees is balanced or a caterpillar, we show that the largest common subtree has $\Omega(\log n)$ leaves. We then handle the general case by proving and applying a Ramsey-type result: that every binary tree contains either a large balanced subtree or a large caterpillar. We also show that there are constants $c, \alpha > 0$ such that, when both trees are balanced, they have a common subtree on cn^α leaves. We conjecture that it is possible to take $\alpha = 1/2$ in the unrooted case, and both $c = 1$ and $\alpha = 1/2$ in the rooted case.

1 Preliminaries

All trees considered in this paper are binary. Although we mainly talk about rooted trees, we introduce the problem in terms of unrooted trees to be consistent with earlier papers on the subject.

1.1 Unrooted phylogenetic trees

A *phylogenetic tree* is a binary, unrooted tree in which the leaves are labelled bijectively with elements from a finite set. All internal vertices of a phylogenetic tree have degree 3. For such a tree T , the set of vertices is denoted by $V(T)$, the set of edges by $E(T)$, and the set of leaves by $L(T)$.

In phylogenetics, it is common to consider isomorphism between trees in a more restricted sense. We say that trees T_1 and T_2 are *isomorphic* (and write $T_1 \cong T_2$) if there is a bijection $\varphi : V(T_1) \rightarrow V(T_2)$ such that

- (i) $\{\varphi(u), \varphi(v)\} \in E(T_2) \iff \{u, v\} \in E(T_1)$,
- (ii) $\varphi(i) = i$ for all leaves $i \in L(T_1)$.

Observe that, while this notion of isomorphism also works for non-binary trees, there can be no isomorphism between trees that have distinct leaf-sets.

For a subset $X \subseteq L(T)$, define the *restriction* of T to X to be the phylogenetic tree $T|X$ with leaf-set $L(T|X) = X$, and the property that there exists an isomorphism (in the sense of the previous paragraph) from a subdivision of $T|X$ to the unique minimal connected subgraph of T containing X . We loosely call the tree $T|X$ a *subtree* of T . Given trees T_1 and T_2 , if X is a subset of $L(T_1) \cap L(T_2)$ of maximum cardinality with the property that $T_1|X \cong T_2|X$, we say that $T_1|X$ (or $T_2|X$) is a *maximum agreement subtree* of T_1 and T_2 . We also define the parameter $\text{mast}\{T_1, T_2\}$ as

$$\text{mast}\{T_1, T_2\} := \max \{|X| : X \subseteq L(T_1) \cap L(T_2), T_1|X \cong T_2|X\}.$$

Now let

$$\text{mast}(n) := \min \{\text{mast}\{T_1, T_2\} : L(T_1) = L(T_2) = \{1, 2, \dots, n\}\}.$$

It was shown by Kubicka, Kubicki, and McMorris in [1] that¹

$$c_1(\log \log n)^{1/2} \leq \text{mast}(n) \leq c_2 \log n, \tag{1}$$

for some positive constants c_1 and c_2 . To see that the upper bound in (1) is tight, consider the case when T_1 is a caterpillar with n leaves and T_2 is a balanced tree of height $\log n$ (to be defined in Section 2): any common subtree must be a caterpillar, and there is no caterpillar of length more than $2 \log n$ in T_2 . The lower bound in (1) was improved by Steel and Székely [2] who showed that $\text{mast}(n) \geq c \log \log n$ for a positive constant c . In fact, in a remark following Theorem 1 in their paper, they mention that a more explicit bound of $\frac{1}{4} \log \log(n-1)$ may be derived, and suggest that a much stronger lower bound of $c \log n$ might hold, for some positive constant c .

Problem 1. Is there a constant $c > 0$ such that any two phylogenetic trees T_1 and T_2 with $L(T_1) = L(T_2) = \{1, 2, \dots, n\}$ have a maximum agreement subtree on at least $c \log n$ leaves?

One of the goals of this paper is to further improve the lower bound in (1). In particular, in Theorem 14, we show that any two phylogenetic trees T_1 and T_2 with leaf-set $\{1, 2, \dots, n\}$ have an agreement subtree on $\Omega(\sqrt{\log n})$ leaves.

¹Logarithms in this paper are always taken with base 2.

1.2 Rooted phylogenetic trees

Next, we develop some terminology for rooted phylogenetic trees. In a rooted phylogenetic tree T , for $|L(T)| > 1$, all internal nodes have degree 3 except the root, which has degree 2. If $|L(T)| = 1$, then T has exactly one vertex which is both its only leaf and root. Let us denote the root of a tree T by $\rho(T)$. For a vertex $u \in V(T)$, we denote by $T^{(u)}$ the subtree of T rooted at u containing all descendants of u in T . We denote by $\ell(u)$ and $r(u)$, respectively, the left and the right children of an internal vertex u of a rooted tree.

For a rooted tree T and vertices x and y in $V(T)$, we define $x \wedge y$ to be the *most recent common ancestor* of x and y . Since $\wedge$ is associative and commutative, we may define the most recent common ancestor of a set $X = \{x_1, x_2, \dots, x_k\} \subseteq V(T)$ to be

$$\bigwedge X := x_1 \wedge x_2 \wedge \dots \wedge x_k.$$

Given rooted trees S and T , we say that S is a subtree of T (and write $S \preceq T$) if there exists an injective map $f : V(S) \rightarrow V(T)$ satisfying

1. $f(x) = x$ for all $x \in L(S)$
2. $f(x \wedge y) = f(x) \wedge f(y)$ for all $x, y \in V(S)$

We say that rooted phylogenetic trees T_1 and T_2 are *isomorphic* if $T_1 \preceq T_2$ and $T_2 \preceq T_1$.

Now we define the *restriction* of T to the set of leaves X as the unique binary, rooted phylogenetic tree $T|X$ having leaf-set X and satisfying $T|X \preceq T$. The rooted maximum agreement subtree and $\text{mast}\{\cdot\}$ are defined as in the unrooted case.

Proposition 2 allows us to recursively construct agreement subtrees (but not necessarily maximum agreement subtrees) of rooted trees.

Proposition 2. *Let T_1 and T_2 be rooted, binary trees, with roots $u := \rho(T_1)$ and $v := \rho(T_2)$, respectively. If $S_\ell \preceq T_1^{(\ell(u))}, T_2^{(\ell(v))}$ and $S_r \preceq T_1^{(r(u))}, T_2^{(r(v))}$, then the tree S with left and right subtrees S_ℓ and S_r , respectively, is such that $S \preceq T_1, T_2$.*

Proof. Let f_ℓ and f_r be maps that realize $S_\ell \preceq T_1^{(\ell(u))}$ and $S_r \preceq T_1^{(r(u))}$, respectively. Then $S \preceq T_1$ is realized by defining a map $f : V(S) \rightarrow V(T_1)$ so that

$$f(x) := \begin{cases} f_\ell(x) & \text{if } x \in V(S_\ell) \\ f_r(x) & \text{if } x \in V(S_r) \\ \rho(T_1) & \text{if } x = \rho(S). \end{cases}$$

A similarly constructed map shows that $S \preceq T_2$. □

We denote the tree S constructed from S_ℓ and S_r as in the above lemma by $S_\ell \circ S_r$.

To prove the results in this paper, we first obtain agreement subtrees of rooted trees (constructed by rooting the given unrooted trees suitably), and then agreement subtrees of unrooted trees by ignoring the roots.

2 When one of the trees is balanced

A rooted, phylogenetic tree is *balanced* if all leaves are at the same distance from the root. For unrooted trees, the definition is analogous. We say that a phylogenetic tree is *balanced* if all leaves are at the same distance from the center of the tree. In this section, we solve Problem 1 when one of the trees is balanced and binary.

2.1 The rooted case

We first consider the case of rooted trees, thus assuming that one tree is a rooted, balanced tree of height m and another is a general rooted, binary tree. In Theorem 8 we prove a result for the unrooted case by appropriately rooting the trees and applying Lemma 3.

In what follows, for nodes $x \in V(T_1)$ and $y \in V(T_2)$, let t_{xy} be the number of elements in the set $L(T_1^{(x)}) \cap L(T_2^{(y)})$.

Lemma 3. *Suppose T_1 is a rooted, balanced, binary tree on a leaf-set of cardinality 2^m , and T_2 is an arbitrary rooted, binary tree on $t > 0$ leaves with $L(T_2) \subseteq L(T_1)$. Then for all $\delta \in (0, 1/2)$, the two trees have a maximum agreement subtree that has at least*

$$\frac{m \log(1 - \delta) + \log t}{1 - \log \delta}$$

leaves.

Proof. Let $g(m, t)$ be the minimum value of $\text{mast}\{T_1, T_2\}$ (over all choices of T_1 and T_2), where T_1 and T_2 are as in the statement of the lemma. Observe that $g(m, t)$ is a monotonically non-decreasing function of t . We show by induction on m that

$$g(m, t) \geq \frac{m \log(1 - \delta) + \log t}{1 - \log \delta}. \quad (2)$$

Base case: If $m = 0$, then $g(m, t) = 1$ and the right-hand-side of (2) is 0. So we may assume that $m > 0$.

Induction step: Let $u := \rho(T_1)$ and $v := \rho(T_2)$. Observe that

$$t = t_{uv} = t_{\ell(u)\ell(v)} + t_{r(u)r(v)} + t_{\ell(u)r(v)} + t_{r(u)\ell(v)}. \quad (3)$$

Without loss of generality, assume that $t_{\ell(u)\ell(v)} + t_{r(u)r(v)} \geq t_{\ell(u)r(v)} + t_{r(u)\ell(v)}$, and $t_{r(u)r(v)} \geq t_{\ell(u)\ell(v)}$. Therefore, by (3), we have

$$t_{r(u)r(v)} \geq \lceil t/4 \rceil. \quad (4)$$

Case 1: $t_{\ell(u)\ell(v)} > 0$.

In this case, we take a maximum agreement subtree S_ℓ of $T_1^{(\ell(u))}$ and $T_2^{(\ell(v))}$, and a maximum agreement subtree S_r of $T_1^{(r(u))}$ and $T_2^{(r(v))}$. We then construct $S = S_\ell \circ S_r$, which by Proposition 2 is an agreement subtree of T_1 and T_2 . Now

$$g(m, t) \geq |L(S)| = |L(S_\ell)| + |L(S_r)| \geq 1 + g(m-1, t_{r(u)r(v)}).$$

By (4), we have

$$g(m, t) \geq 1 + g(m-1, \lceil t/4 \rceil).$$

Therefore, applying the induction hypothesis, we obtain

$$\begin{aligned} g(m, t) &\geq 1 + \frac{(m-1) \log(1-\delta) + \log(t/4)}{1 - \log \delta} \\ &= \frac{m \log(1-\delta) + \log t}{1 - \log \delta} + \frac{-1 - \log(1-\delta) - \log \delta}{1 - \log \delta} \\ &> \frac{m \log(1-\delta) + \log t}{1 - \log \delta}. \end{aligned}$$

Case 2: $t_{\ell(u)\ell(v)} = 0$.

From now on, we assume that $t_{r(u)\ell(v)}$ is non-zero; otherwise, together with the assumption of this case, it would contradict the hypothesis that $L(T_2) \subseteq L(T_1)$.

Subcase 2.1: $t_{\ell(u)r(v)} + t_{r(u)\ell(v)} \geq \delta t$ and $t_{\ell(u)r(v)} > 0$. Also, without loss of generality, assume that $t_{r(u)\ell(v)} \geq t_{\ell(u)r(v)}$, so that $t_{r(u)\ell(v)} \geq \delta t/2$.

In this case, we construct $S := S_\ell \circ S_r$, where S_ℓ is a rooted maximum agreement subtree of $T_1^{(\ell(u))}$ and $T_2^{(r(v))}$, and S_r is a rooted maximum agreement subtree of $T_1^{(r(u))}$ and $T_2^{(\ell(v))}$. Therefore,

$$\begin{aligned} g(m, t) &\geq |L(S_\ell)| + |L(S_r)| \\ &\geq 1 + g(m-1, \lceil \delta t/2 \rceil) \\ &\geq 1 + \frac{(m-1) \log(1-\delta) + \log(\delta t/2)}{1 - \log \delta} \\ &\geq \frac{m \log(1-\delta) + \log t}{1 - \log \delta} + \frac{-\log(1-\delta)}{1 - \log \delta} \\ &> \frac{m \log(1-\delta) + \log t}{1 - \log \delta}. \end{aligned}$$

Subcase 2.2: $t_{\ell(u)r(v)} + t_{r(u)\ell(v)} < \delta t$. In this case, $t_{r(u)r(v)} = t - t_{\ell(u)\ell(v)} - t_{\ell(u)r(v)} - t_{r(u)\ell(v)} > (1-\delta)t$.

Let S be a rooted maximum agreement subtree of $T_1^{(r(u))}$ and $T_2^{(r(v))}$. We have

$$\begin{aligned} g(m, t) &\geq |L(S)| \\ &= g(m-1, \lceil (1-\delta)t \rceil) \\ &\geq \frac{(m-1) \log(1-\delta) + \log(1-\delta)t}{1 - \log \delta} \\ &= \frac{m \log(1-\delta) + \log t}{1 - \log \delta} \end{aligned}$$

Subcase 2.3: $t_{\ell(u)r(v)} = 0$.

Let S be a rooted maximum agreement subtree of $T_1^{(r(u))}$ and $T_2^{(v)}$. Therefore,

$$\begin{aligned}
g(m, t) &\geq |L(S)| \\
&= g(m-1, t) \\
&\geq \frac{(m-1)\log(1-\delta) + \log t}{1 - \log \delta} \\
&= \frac{m\log(1-\delta) + \log t}{1 - \log \delta} + \frac{-\log(1-\delta)}{1 - \log \delta} \\
&> \frac{m\log(1-\delta) + \log t}{1 - \log \delta}.
\end{aligned}$$

With this we complete all subcases of the induction step. Therefore (2) holds and the lemma is proved. $\square$

An immediate consequence of the above lemma is the following corollary.

Corollary 4. *For $\delta \in (0, 1/2)$, set*

$$\alpha := \frac{1 + \log(1-\delta)}{1 - \log \delta}. \quad (5)$$

If T_1 is a rooted, balanced, binary tree on a leaf-set of cardinality 2^m , and T_2 is an arbitrary rooted, binary tree on 2^m leaves such that $L(T_2) = L(T_1)$, then T_1 and T_2 have a maximum agreement subtree on at least αm leaves.

Remark 5. We found numerically that the maximum value of α is approximately 0.2055 obtained when δ is approximately 0.1705.

Remark 6. An algorithm to construct an agreement tree (though not necessarily a maximum agreement subtree) is implicit in the proof of Lemma 3. Observe that in each of Case 1 and Subcase 2.1, we may take the agreement subtree S_ℓ to be a tree with a single leaf (e.g. any leaf from $L(T_1^{(\ell(u))}) \cap L(T_2^{(\ell(v))})$ in Case 1 and any leaf from $L(T_1^{(\ell(u))}) \cap L(T_2^{(r(v))})$ in Subcase 2.1). Such a choice gives us an agreement subtree that is a caterpillar of length αm in Corollary 4.

We explicitly describe a recursive algorithm, which we call **Match1**. The algorithm takes as input two rooted, binary trees, the first one being balanced, and returns a set of leaves in a common subtree that is a caterpillar. As in Lemma 3, algorithm **Match1** also depends on a parameter $\delta \in (0, 1/2)$.

Algorithm $\text{Match1}(T_1^{(u)}, T_2^{(v)})$

- 1: if $|L(T_1^{(u)})| = 1$ or $|L(T_1^{(v)})| = 1$ then return $L(T_1^{(u)}) \cap L(T_1^{(v)})$.
- 2: if necessary, interchange left and right subtrees in $T_1^{(u)}$ and/or $T_2^{(v)}$ so that $t_{\ell(u)r(v)} + t_{r(u)\ell(v)} \leq t_{\ell(u)\ell(v)} + t_{r(u)r(v)}$ and $t_{\ell(u)\ell(v)} \leq t_{r(u)r(v)}$.
- 3: if $(t_{\ell(u)\ell(v)} > 0)$ then
 - (a) select any leaf z from $L(T_1^{(\ell(u))}) \cap L(T_1^{(\ell(v))})$,
 - (b) return $\{z\} \cup \text{Match1}(T_1^{(r(u))}, T_2^{(r(v))})$.
- 4: if $t_{r(u)\ell(v)} = 0$ then return $\text{Match1}(T_1^{(u)}, T_2^{(r(v))})$.
- 5: if $t_{\ell(u)r(v)} = 0$ then return $\text{Match1}(T_1^{(r(u))}, T_2^{(v)})$.
- 6: if $(t_{\ell(u)r(v)} + t_{r(u)\ell(v)} \geq \delta t_{uv})$ then
 - (a) if necessary, interchange the left and the right subtrees of both $T_1^{(u)}$ and $T_2^{(v)}$ so that $t_{\ell(u)r(v)} \leq t_{r(u)\ell(v)}$,
 - (b) select any leaf z from $L(T_1^{(\ell(u))}) \cap L(T_1^{(r(v))})$,
 - (c) return $\{z\} \cup \text{Match1}(T_1^{(r(u))}, T_2^{(\ell(v))})$.
- 7: return $\text{Match1}(T_1^{(r(u))}, T_2^{(r(v))})$.

Steel and Warnow [3] devised an efficient polynomial time algorithm for finding the maximum agreement subtree of two given binary trees. Our algorithm is not optimal, but it is easy to analyze; moreover, it is easy to guarantee a lower bound on the returned value. We show how the value of α in Lemma 3 may also be obtained by analyzing the algorithm.

Alternative proof of Corollary 4. Set $x := \rho(T_1)$ and $y := \rho(T_2)$. We now analyze the execution of the a call to $\text{Match1}(T_1^{(x)}, T_2^{(y)})$.

First observe that, each time an instance of algorithm Match1 is being executed, it calls itself recursively only once in that instance. That happens, say k times, each time going deeper in the recursion levels, until a base case is reached in line 1. Thus, we may define two sequences of nodes $x = x_0, x_1, x_2, \dots, x_k$ and $y = y_0, y_1, y_2, \dots, y_k$ that correspond to the roots of the trees passed as arguments in each triggered call. That is, $\text{Match1}(T_1^{(x_0)}, T_2^{(y_0)})$ calls $\text{Match1}(T_1^{(x_1)}, T_2^{(y_1)})$, which in turn calls $\text{Match1}(T_1^{(x_2)}, T_2^{(y_2)})$, and so on. Note that the nodes in each sequence need not be distinct. For example, if Match1 is called from line 4, then $x_{i+1} = x_i$; and similarly, if Match1 is called from line 5, then $y_{i+1} = y_i$.

As a shorthand notation, define

$$t_i := t_{x_i y_i}.$$

Now suppose $\text{Match1}(T_1^{(u)}, T_2^{(v)})$ is being called with $u = x_i$ and $v = y_i$. Using our notation, we have $t_i = t_{uv}$. For each possibility of calling Match1 recursively, we obtain a lower bound for t_{i+1} in terms of t_i .

After executing line 2, we have $t_{r(u)r(v)} \geq t_{uv}/4$. Hence, if the recursive call in line 3b is triggered, we have

$$t_{i+1} \geq t_i/4. \quad (6)$$

If the recursive call in line 4 is triggered, it is because $t_{\ell(u)\ell(v)} = 0$ and $t_{r(u)\ell(v)} = 0$, which implies $t_{ur(v)} = t_{uv}$. Hence, in that case, we must have

$$t_{i+1} = t_i. \quad (7)$$

Similarly, if the recursive call in line 5 is triggered, we have $t_{r(u)v} = t_{uv}$, which also implies (7). The conditions in lines 6 and 6a imply that $t_{r(u)\ell(v)} \geq \delta t_{uv}/2$. Hence, if the recursive call in line 6c is made, we must have

$$t_{i+1} \geq \delta t_i/2. \quad (8)$$

In line 7, since $t_{\ell(u)r(v)} + t_{r(u)\ell(v)} < \delta t_{uv}$ and $t_{\ell(u)\ell(v)} = 0$, we have $t_{r(u)r(v)} > (1 - \delta)t_{uv}$. Hence, if Match1 is called from line 7, then we have

$$t_{i+1} > (1 - \delta)t_i. \quad (9)$$

Now suppose that, during the entire execution of the recursive algorithm, line 3b is executed a times, line 4 is executed b times, line 5 is executed c times, line 6c is executed d times, and line 7 is executed e times. Since a new leaf z is returned each time one of the lines 3b or 6c is executed, the set returned by the outermost call $\text{Match1}(T_1^{(x)}, T_2^{(y)})$ (when the execution halts) contains precisely $a + d + 1$ leaves. Therefore, it is enough to show the following.

Claim 7. $a + d > \alpha m$.

To prove the claim consider the sequence $t_0, t_1, \dots, t_k$. For each i in $\{0, 1, \dots, k-1\}$, we know that t_{i+1} satisfies one of (6), (7), (8) or (9). Therefore, we have

$$t_k \geq t_0 \left(\frac{1}{4}\right)^a \left(\frac{\delta}{2}\right)^d (1 - \delta)^e. \quad (10)$$

Now observe that $t_0 = 2^m$. Also, since the k -th recursive call is a base case, we have $t_k = 1$. Moreover, because $\delta < 1/2$, we have $1/4^a > (\delta/2)^a$. Using these observations and the fact that $e \leq m$, equation (10) yields

$$1 > 2^m \left(\frac{\delta}{2}\right)^{a+d} (1 - \delta)^m.$$

Solving for $a + d$, we obtain

$$a + d > \left(\frac{1 + \log(1 - \delta)}{1 - \log \delta}\right)m = \alpha m.$$

The claim is proved, and the corollary follows. $\square$

2.2 The unrooted case

We now consider the case when one of the trees is unrooted and balanced. We define two classes of unrooted, balanced trees. The center of a tree may be either a single vertex or a pair of adjacent vertices. Let $m \geq 0$ be an integer. When all leaves of a tree are at distance m from the center and the center is a single vertex, we say that the tree is in class $\mathcal{C}_m$. When all leaves are at distance m from the center and the center is a pair of adjacent vertices, we say the phylogenetic tree is in class $\mathcal{B}_{m+1}$. By construction, trees in the class $\mathcal{C}_m$ have $3 \times 2^{m-1}$ leaves, and trees in the class $\mathcal{B}_m$ have 2^m leaves.

Theorem 8. *If T_1 is a balanced phylogenetic tree on n leaves, and T_2 is an arbitrary phylogenetic tree on the same leaf-set, then they have an agreement subtree on at least $\alpha \log \frac{2n}{3}$ leaves, where α is the constant defined in (5).*

Proof. If T_1 is in class $\mathcal{B}_m$, for some m , then $n = 2^m$. Let $\{x, y\}$ be its central edge. We add a new vertex z , and replace the edge $\{x, y\}$ by edges $\{x, z\}$ and $\{y, z\}$, and root the tree at z . For T_2 , we add a new vertex w , replace an arbitrary edge $\{u, v\}$ by edges $\{u, w\}$ and $\{v, w\}$, and root T_2 at w . Notice that, for any rooted agreement subtree of $T_1^{(z)}$ and $T_2^{(w)}$, we may ignore the root and obtain an unrooted agreement subtree of T_1 and T_2 . Applying Lemma 3 to $T_1^{(z)}$ and $T_2^{(w)}$ gives a lower bound of αm on the size of the maximum agreement subtree of $T_1^{(z)}$ and $T_2^{(w)}$. The desired bound follows.

If T_1 is in class $\mathcal{C}_m$, for some m , then $n = 3 \times 2^{m-1}$. Let z be the center of T_1 . Let X be the set of leaves in two of the three branches rooted at z . Note that $T_1|X$ is in class $\mathcal{B}_m$ and $T_2|X$ is an arbitrary phylogenetic tree. Proceeding as in the above paragraph, we obtain a lower bound of αm on the size of the maximum agreement subtree of $T_1|X$ and $T_2|X$. Hence, T_1 and T_2 have an agreement subtree on at least $\alpha \log \frac{2n}{3}$ leaves. $\square$

The following proposition for the case when one of the trees is “almost balanced” is proved with little extra effort.

Proposition 9. *For every $k > 0$, there is a constant $\alpha_k > 0$ such that, if T_1 and T_2 are binary trees on the same leaf-set of cardinality n , and T_1 has radius at most $k \log n - 1$, then they have a maximum agreement subtree on at least $\alpha_k \log n$ leaves.*

Proof. In tree T_1 , we subdivide the central edge (if it has a central edge) or an edge adjacent to the center (if its center is a single vertex), and root the tree at the newly inserted vertex of degree 2. (We have bounded the radius of T_1 by $k \log n - 1$ and not $k \log n$ only to allow the possibility that when we root T_1 , its radius may increase by 1.) We root T_2 by subdividing an arbitrarily chosen edge. We then construct a rooted, balanced, binary tree T'_1 of height $k \log n$ that contains T_1 as a subtree (in the sense that $T_1 \preceq T'_1$). Now by Lemma 3, we assert that T'_1 and T_2 (hence also T_1 and T_2) have an agreement subtree on at least

$$\frac{k \log n \log(1 - \delta) + \log n}{1 - \log \delta} = \left(\frac{1 + k \log(1 - \delta)}{1 - \log \delta} \right) \log n$$

leaves. We select δ sufficiently small to satisfy $1 + k \log(1 - \delta) > 0$, and set

$$\alpha_k := \frac{1 + k \log(1 - \delta)}{1 - \log \delta}.$$

Then there is an agreement subtree on at least $\alpha_k \log n$ leaves. Indeed, the above value of α_k may also be obtained by (re)analyzing algorithm **Match1** as in the alternative proof of Corollary 4. $\square$

3 General binary trees

Our approach to general binary trees is based on the following intuition: every binary tree has large diameter or contains (as a restriction) a balanced subtree of large height.

For $0 \leq k \leq h$, let $f(h, k)$ be the maximum number of leaves a rooted tree of height at most h can have so that no restriction of the tree is a balanced, binary tree of height more than k .

Lemma 10. *If $h = k$ or $k = 0$, then $f(h, k) = 2^k$. If $0 < k < h$, then*

$$f(h, k) = \sum_{i=0}^k \binom{h-i-1}{k-i} 2^i.$$

Proof. We claim the following recurrence for $f(h, k)$:

$$f(h, k) = \begin{cases} 2^k & \text{if } h = k \text{ or } k = 0, \\ f(h-1, k) + f(h-1, k-1) & \text{if } 0 < k < h. \end{cases} \quad (11)$$

This is proved as follows. If $h = k$ or $k = 0$, then we have $f(h, k) = 2^k$, the extremal tree being the rooted, balanced tree of height k .

Now suppose that $h > k > 0$. We first prove that $f(h, k) \leq f(h-1, k) + f(h-1, k-1)$. Let T be a binary tree of height at most h with more than $f(h-1, k) + f(h-1, k-1)$ leaves. Suppose T has x leaves in the left subtree and y leaves in the right subtree. Without loss of generality assume $y \leq x$. If $x > f(h-1, k)$, then the left subtree of T would have a restriction to a balanced, binary tree of height $k+1$. Therefore, we may assume that $x \leq f(h-1, k)$, which implies $f(h-1, k-1) < y \leq x$. It follows that both the left and the right subtrees have restrictions to balanced trees of height k , and that T has a restriction to a balanced tree of height $k+1$, which is a contradiction.

Next we show that $f(h, k) \geq f(h-1, k) + f(h-1, k-1)$. Consider the tree $T(h, k)$ defined as follows: if $h = k$ or $k = 0$, then $T(h, k)$ is a balanced, binary tree of height k ; otherwise, its left subtree is an extremal tree for parameters $h-1$ and k , and its right subtree is an extremal tree for parameters $h-1$ and $k-1$. Thus $T(h, k)$ has precisely $f(h-1, k) + f(h-1, k-1)$ leaves, and does not contain a restriction that is a balanced tree of height more than k .

Thus we have $f(h, k) = f(h-1, k) + f(h-1, k-1)$ for $0 < k < h$, and the tree $T(h, k)$ constructed above is an example of an extremal tree for parameters h and k . In fact the above arguments, together with induction on $h + k$, show that $T(h, k)$ is the unique such tree. We skip the details.

Now the solution to the recurrence relation is obtained by expanding it until all terms are expressed as $f(i, i) = 2^i$ for some $i > 0$ or $f(j, 0) = 1$ for some $j > 0$.

Figure 1: An illustration for the recurrence in (11)

In Figure 1 above, each directed path from the point (h, k) to (i, i) contributes the term $f(i, i) = 2^i$, and there are $\binom{h-i-1}{k-i}$ such paths; similarly every path from (h, k) to $(j, 0)$ contributes $f(j, 0) = 1$, and there are $\binom{k+j-1}{j}$ such paths. Hence, for $0 < k < h$, we have

$$f(h, k) = \sum_{i=1}^k \binom{h-i-1}{k-i} 2^i + \sum_{j=0}^{h-k-1} \binom{k+j-1}{j}$$

Since the second sum is $\binom{h-1}{k}$, the desired bound follows. $\square$

Corollary 11. *For $1 \leq k \leq h$, we have $f(h, k) \leq (2h)^k$.*

Proof. We apply Lemma 10. If $k = 1$, then $f(h, k) = h + 1 \leq (2h)^k$. If $1 < k < h$, then we have

$$f(h, k) = \sum_{i=0}^k \binom{h-i-1}{k-i} 2^i < \binom{h}{k} \sum_{i=0}^k 2^i < (2h)^k.$$

If $k = h$, then $f(h, k) = 2^k \leq (2h)^k$. $\square$

Define $\phi(n, a) = \frac{(\log n)^a}{2}$ and $\psi(n, b) = \frac{(\log n)^b}{\log \log n}$.

Corollary 12. *Given any $a, b \in (0, 1)$ such that $a + b = 1$, every tree with $n > 2$ leaves contains either a path of length at least $(\log n)^{\psi(n, b)}$ or a balanced subtree of height at least $\phi(n, a)$.*

Proof. Let $a, b \in (0, 1)$ such that $a + b = 1$. Let $k \leq \phi(n, a)$ and $h \leq (\log n)^{\psi(n, b)}$. We have

$$\begin{aligned}
k \log(2h) &= k + k \log h \\
&\leq \phi(n, a) + \phi(n, a) \psi(n, b) \log \log n \\
&= \frac{(\log n)^a}{2} + \frac{\log n}{2} \\
&< \log n.
\end{aligned} \tag{12}$$

Hence, by Corollary 11, we conclude that $f(h, k) < n$. Now the corollary follows. $\square$

Proposition 13. *If T_1 and T_2 are binary trees on the same leaf-set of cardinality n , and T_1 is a caterpillar, then they have a maximum agreement subtree on at least $\frac{1}{3} \log n$ leaves.*

Proof. The proof of this fact goes along the lines of the proof of Theorem 1 in Steel and Székely [2]. We sketch it here. We embed T_1 and T_2 in the plane so that the leaves of T_1 are on one side of the longest path in T_1 . Without loss of generality, suppose that the leaves of T_1 appear in the order $1, 2, \dots, n$. The embedding of T_2 imposes a circular order on its leaves. We cut this circular order arbitrarily to get a linear order $i_1, i_2, \dots, i_n$. Next we find the longest monotone subsequence of $i_1, i_2, \dots, i_n$; it has length at least $\sqrt{n}$ by the Erdős-Szekeres Theorem [4]. Let X be the set of leaves in this subsequence. We restrict T_1 and T_2 to X obtaining $T_1|X$ and $T_2|X$. Notice that $T_1|X$ is still a caterpillar. We further restrict both trees to $Y \subseteq X$ so that $T_2|Y$ is a caterpillar with a maximum number of leaves. Thus $|Y|$ is at least $\log n$ (the extremal case being when $T_2|X$ is balanced). Now both $T_1|Y$ and $T_2|Y$ are caterpillars (see Figure 2 below). Now let $y_1, y_2, \dots, y_k$ be the elements of Y in the order they appear in the embedding of T_1 .

Figure 2: The embeddings of $T_1|Y$ and $T_2|Y$.

In Figure 2, we can see that there are three maximal agreement caterpillars, namely, caterpillars with leaf-sets $\{y_1, y_2, \dots, y_i\}$, $\{y_i, y_{i+1}, \dots, y_j\}$ and $\{y_j, y_{j+1}, \dots, y_k\}$. One of them must have length at least $(k + 2)/3 \geq \frac{1}{3} \log n$. $\square$

Theorem 14. *If T_1 and T_2 are binary trees on the same leaf-set of cardinality $n > 2$, then they have a maximum agreement subtree having at least $\frac{\alpha}{2}\sqrt{\log n} + \alpha \log \frac{2}{3}$ leaves.*

Proof. Applying Corollary 12 (with $a = b = 1/2$), one of the trees must contain a balanced subtree of height at least $\phi(n, 1/2)$ or a path of length at least $(\log n)^{\psi(n, 1/2)}$. Suppose that one of the trees contains a balanced subtree of height at least $\phi(n, 1/2)$. Let A be the leaf-set of such a balanced subtree. Therefore, after restricting the other tree to A , we can claim by Theorem 8 that T_1 and T_2 have a common subtree on at least $\alpha\phi(n, 1/2) + \alpha \log \frac{2}{3}$ leaves from A .

If such a balanced subtree does not exist in either of the two trees, then there is a path (and hence a caterpillar) of length at least $(\log n)^{\psi(n, 1/2)}$ in one of the trees. We restrict both trees to the set of leaves in this caterpillar. Therefore, by Proposition 13, there must be a common subtree on at least $\frac{1}{3}\psi(n, 1/2) \log \log n = \frac{1}{3}\sqrt{\log n}$ leaves. Taking the maximum value of α as in Remark 5, this is a quantity larger than the desired bound. $\square$

Corollary 15. *Any given trees $T_1, T_2, \dots, T_k$, where $k > 2$, on the same leaf set of cardinality n have a maximum agreement subtree on $\Omega(\log^{k-1} n)$ leaves.*

Proof. By Theorem 14, there is a common subtree $T_{1,2}$ of T_1 and T_2 on $\Omega(\sqrt{\log n})$ leaves. In fact $T_{1,2}$ is a caterpillar. This is so in either of the two cases considered in Theorem 14. If one of the trees contains a sufficiently large balanced subtree, then by **Algorithm Match1**, we have a common caterpillar subtree on $\Omega(\sqrt{\log n})$ leaves. If neither of the trees T_1 and T_2 contains a sufficiently large balanced subtree, then we restricted one of the trees to a sufficiently large caterpillar. Thus by construction, there is a common caterpillar subtree on $\Omega(\sqrt{\log n})$ leaves. We then restrict T_3 to the leaf set of $T_{1,2}$. Now by repeated applications of Proposition 13, $T_{1,2}$ and T_3 must have a common caterpillar subtree, say $T_{1,2,3}$, on $\Omega(\log(\sqrt{\log n})) \sim \Omega(\log \log n)$ leaves, and $T_{1,2,3}$ and T_4 have a common caterpillar subtree on $\Omega(\log \log \log n)$ leaves, and so on. $\square$

4 When both trees are balanced

We now investigate the size of a maximum agreement subtree of two balanced, binary trees. In this case, in Theorem 19 we obtain a much better bound than that of Theorem 8.

Lemma 16. *Suppose T_1 and T_2 are rooted, balanced, binary trees of height m_1 and m_2 , respectively. Suppose that $|L(T_1) \cap L(T_2)| = t > 0$. Then for all $\delta \in (0, \frac{1}{4})$, the two trees have a rooted maximum agreement subtree on at least $2^{g(m_1, m_2, t)}$ leaves, where*

$$g(m_1, m_2, t) := \frac{(m_1 + m_2) \log(1 - 3\delta) + \log t}{\log(1 - 3\delta) - \log \delta}.$$

Proof. Let $M(m_1, m_2, t)$ be the minimum value of $\text{mast}\{T_1, T_2\}$ (over all choices of T_1 and T_2), where T_1 and T_2 are as in the statement of the lemma. Observe that $M(m_1, m_2, t)$ is a monotonically non-decreasing function of t . We show the result by induction on $m_1 + m_2$.

Base case: When $m_1 + m_2 \in \{0, 1\}$, at least one of the trees has a single vertex (which is its leaf and root), hence $\text{mast}\{T_1, T_2\} = 1$. Also, since $t = 1$, we have $g(m_1, m_2, t) \leq 0$, and the claim is true. So we assume below that $m_1 \geq 1$ and $m_2 \geq 1$.

Induction step: Let $u := \rho(T_1)$ and $v := \rho(T_2)$. As in Theorem 8, we have $t = t_{uv} = t_{\ell(u)\ell(v)} + t_{r(u)r(v)} + t_{\ell(u)r(v)} + t_{r(u)\ell(v)}$ and we assume, without loss of generality, that $t_{\ell(u)\ell(v)} + t_{r(u)r(v)} \geq t_{\ell(u)r(v)} + t_{r(u)\ell(v)}$ and $t_{r(u)r(v)} \geq t_{\ell(u)\ell(v)}$ to obtain

$$t_{r(u)r(v)} \geq \lceil t/4 \rceil. \quad (13)$$

Case 1: $t_{\ell(u)\ell(v)} \geq \delta t$.

By (13), we also have $t_{r(u)r(v)} \geq \delta t$. In this case, we take a maximum agreement subtree S_ℓ of $T_1^{(\ell(u))}$ and $T_2^{(\ell(v))}$, and a maximum agreement subtree S_r of $T_1^{(r(u))}$ and $T_2^{(r(v))}$. We then construct $S = S_\ell \circ S_r$, which by Proposition 2 is an agreement subtree of T_1 and T_2 . Therefore, we have

$$\begin{aligned} M(m_1, m_2, t) &\geq 2M(m_1 - 1, m_2 - 1, \lceil \delta t \rceil) \\ &\geq 2 \times 2^{g(m_1 - 1, m_2 - 1, \lceil \delta t \rceil)} \\ &\geq 2^{(1 + g(m_1 - 1, m_2 - 1, \lceil \delta t \rceil))} \\ &\geq 2^{g(m_1, m_2, t)}, \end{aligned}$$

where the last step follows from

$$\begin{aligned} 1 + g(m_1 - 1, m_2 - 1, \lceil \delta t \rceil) &= 1 + \frac{(m_1 - 1 + m_2 - 1) \log(1 - 3\delta) + \log(\delta t)}{\log(1 - 3\delta) - \log \delta} \\ &= \frac{(m_1 + m_2) \log(1 - 3\delta) + \log t - \log(1 - 3\delta)}{\log(1 - 3\delta) - \log \delta} \\ &> g(m_1, m_2, t), \end{aligned}$$

where the last inequality requires that $\delta \in (0, \frac{1}{4})$.

Case 2: $t_{\ell(u)r(v)} \geq \delta t$ and $t_{r(u)\ell(v)} \geq \delta t$.

The calculation in this case is identical to that of Case 1, so we omit it.

Case 3: $t_{\ell(u)r(v)} < \delta t$ and $t_{r(u)\ell(v)} < \delta t$.

Since Case 1 has been examined, we assume that $t_{\ell(u)\ell(v)} < \delta t$, which implies $t_{r(u)r(v)} > (1 - 3\delta)t$. Since $\text{mast}\{T_1, T_2\}$ must be at least $\text{mast}\{T_1^{(r(u))}, T_2^{(r(v))}\}$, we have $M(m_1, m_2, t) \geq M(m_1 - 1, m_2 - 1, \lceil (1 - 3\delta)t \rceil)$. Now the result follows from the assumption that $\delta \in (0, \frac{1}{4})$ and the following:

$$\begin{aligned} &g(m_1 - 1, m_2 - 1, \lceil (1 - 3\delta)t \rceil) \\ &\geq \frac{(m_1 - 1 + m_2 - 1) \log(1 - 3\delta) + \log(1 - 3\delta)t}{\log(1 - 3\delta) - \log \delta} \\ &= \frac{(m_1 + m_2) \log(1 - 3\delta) + \log t - \log(1 - 3\delta)}{\log(1 - 3\delta) - \log \delta} \\ &> g(m_1, m_2, t). \end{aligned}$$

Case 4: $t_{\ell(u)r(v)} < \delta t$ and $t_{r(u)\ell(v)} \geq \delta t$.

Since Case 1 has been examined, we assume that $t_{\ell(u)\ell(v)} < \delta t$, which implies $t_{r(u)\ell(v)} + t_{r(u)r(v)} > (1 - 2\delta)t$. In this case, since $\text{mast}\{T_1, T_2\}$ must be at least $\text{mast}\{T_1^{(r(u))}, T_2\}$, we can write $M(m_1, m_2, t) \geq M(m_1 - 1, m_2, \lceil (1 - 2\delta)t \rceil)$. Now the result follows from the assumption that $\delta \in (0, \frac{1}{4})$ and the following:

$$\begin{aligned}
& g(m_1 - 1, m_2, \lceil (1 - 2\delta)t \rceil) \\
\geq & \frac{(m_1 - 1 + m_2) \log(1 - 3\delta) + \log(1 - 2\delta)t}{\log(1 - 3\delta) - \log \delta} \\
= & \frac{(m_1 + m_2) \log(1 - 3\delta) + \log t + \log(1 - 2\delta) - \log(1 - 3\delta)}{\log(1 - 3\delta) - \log \delta} \\
> & g(m_1, m_2, t).
\end{aligned}$$

Case 5: $t_{\ell(u)r(v)} \geq \delta t$ and $t_{r(u)\ell(v)} < \delta t$.

The analysis of this case is similar to Case 4, except that we have the inequality $M(m_1, m_2, t) \geq M(m_1, m_2 - 1, \lceil (1 - 2\delta)t \rceil)$. $\square$

Corollary 17. *Let*

$$\delta \in \left(0, \frac{1}{3} - \frac{1}{3\sqrt{2}}\right) \quad \text{and} \quad \beta := \left(\frac{1 + 2\log(1 - 3\delta)}{\log(1 - 3\delta) - \log \delta}\right).$$

If T_1 and T_2 are rooted, balanced, binary trees on the same leaf-set of cardinality 2^m , then T_1 and T_2 have a maximum agreement subtree on at least $2^{\beta m}$ leaves.

Proof. We set $m_1 = m_2 = m$ and $t = 2^m$ in Lemma 16. Moreover, we now require δ to be less than $\left(\frac{1}{3} - \frac{1}{3\sqrt{2}}\right)$ (which is less than $1/4$) so as to ensure that β is positive. $\square$

As in Section 2, we present algorithm **Match2** that closely follows the recursions in the proof of Lemma 16. It takes as input two rooted, balanced, binary trees, and returns a set of leaves in a common subtree. Algorithm **Match2** depends on a real positive δ , which we require to be sufficiently small for the algorithm to give a desired bound on the size of a common subtree. The algorithm is somewhat greedy and suboptimal. The analysis of the performance of **Match2** makes Lemma 16 much more transparent, giving an alternative proof of Corollary 17. We then apply the corollary to prove the main results of this section for unrooted, balanced (or “almost balanced”) trees.

Algorithm $\text{Match2}(T_1^{(u)}, T_2^{(v)})$

- 1: if $|L(T_1^{(u)})| = 1$ or $|L(T_1^{(v)})| = 1$ then
return $L(T_1^{(u)}) \cap L(T_1^{(v)})$.
- 2: if necessary, interchange left and right subtrees in $T_1^{(u)}$ and/or $T_2^{(v)}$ so that
 $t_{\ell(u)r(v)} + t_{r(u)\ell(v)} \leq t_{\ell(u)\ell(v)} + t_{r(u)r(v)}$ and $t_{\ell(u)\ell(v)} \leq t_{r(u)r(v)}$.
- 3: if $(t_{\ell(u)\ell(v)} \geq \delta t_{uv}$ and $t_{r(u)r(v)} \geq \delta t_{uv})$ then
return $\text{Match2}(T_1^{(\ell(u))}, T_2^{(\ell(v))}) \cup \text{Match2}(T_1^{(r(u))}, T_2^{(r(v))})$.
- 4: if $(t_{\ell(u)r(v)} \geq \delta t_{uv}$ and $t_{r(u)\ell(v)} \geq \delta t_{uv})$ then
return $\text{Match2}(T_1^{(\ell(u))}, T_2^{(r(v))}) \cup \text{Match2}(T_1^{(r(u))}, T_2^{(\ell(v))})$.
- 5: if $(t_{\ell(u)r(v)} < \delta t_{uv}$ and $t_{r(u)\ell(v)} < \delta t_{uv})$ then
return $\text{Match2}(T_1^{(r(u))}, T_2^{(r(v))})$.
- 6: if $(t_{\ell(u)r(v)} < \delta t_{uv}$ and $t_{r(u)\ell(v)} \geq \delta t_{uv})$ then
return $\text{Match2}(T_1^{(r(u))}, T_2^{(v)})$.
- 7: if $(t_{\ell(u)r(v)} \geq \delta t_{uv}$ and $t_{r(u)\ell(v)} < \delta t_{uv})$ then
return $\text{Match2}(T_1^{(u)}, T_2^{(r(v))})$.

We now analyze the above algorithm to compute β in Corollary 17 more transparently.

Alternative proof of Corollary 17. We prove the result by analyzing Match2 . In the beginning, we call $\text{Match2}(T_1^{(x)}, T_2^{(y)})$, where $x := \rho(T_1)$ and $y := \rho(T_2)$. Let $\mathcal{T}$ be the tree of recursive calls to Match2 constructed as follows: the pair (x, y) is the root of $\mathcal{T}$. If $\text{Match2}(T_1^{(u)}, T_2^{(v)})$ is called during the execution of the algorithm, then (u, v) is a vertex of $\mathcal{T}$. If $\text{Match2}(T_1^{(u)}, T_2^{(v)})$ calls $\text{Match2}(T_1^{(u')}, T_2^{(v')})$, then (u', v') is a child of (u, v) . The leaf vertices of $\mathcal{T}$ correspond to the function calls that return in line 1. Observe that in line 1, a set containing a single new leaf is returned. By construction, the number of leaves in the common subtree returned by Match2 is precisely the number of leaves of $\mathcal{T}$.

The ideas in this lemma are similar to those in the alternative proof of Corollary 4. We consider an arbitrary root-to-leaf path in $\mathcal{T}$ and we show that it branches at least βm times. We then conclude that $\mathcal{T}$ has at least $2^{\beta m}$ leaves, thereby proving the theorem.

Now consider an arbitrary root-to-leaf path $(x_0, y_0), (x_1, y_1), \dots, (x_k, y_k)$ in $\mathcal{T}$, where $(x_0, y_0) := (x, y)$. As a shorthand notation, define

$$t_i := t_{x_i y_i}.$$

Now suppose $\text{Match2}(T_1^{(u)}, T_2^{(v)})$ is being called with $u = x_i$ and $v = y_i$. Using our notation, we have $t_i = t_{uv}$. For each possibility of calling Match2 recursively, we obtain a lower bound for t_{i+1} in terms of t_i .

First observe that, as in the case of **Match1**, we relabel $\ell(u), r(u)$ and $\ell(v), r(v)$ so that we have $t_{\ell(u)\ell(v)} + t_{r(u)r(v)} \geq t_{uv}/2$ and $t_{r(u)r(v)} \geq t_{\ell(u)\ell(v)}$ (which implies $t_{r(u)r(v)} \geq t_{uv}/4$). Hence, for the choice of δ , we have

$$t_{r(u)r(v)} \geq t_{uv}/4 \geq \delta t_{uv}. \quad (14)$$

If a recursive call in line 3 is triggered, then (x_{i+1}, y_{i+1}) is either $(\ell(u), \ell(v))$ or $(r(u), r(v))$. In both cases, under the conditions in line 3, we have

$$t_{i+1} \geq \delta t_i. \quad (15)$$

Similarly, if a recursive call in line 4 is triggered, then we also have (15).

After lines 3 and 4, we must have $t_{\ell(u)\ell(v)} < \delta t_{uv}$ because $t_{\ell(u)\ell(v)} \leq t_{r(u)r(v)}$ and the condition in line 3 has failed.

If the recursive call in line 5 is triggered, then $(x_{i+1}, y_{i+1}) = (r(u), r(v))$, and

$$t_{i+1} \geq (1 - 3\delta)t_i, \quad (16)$$

because $t_{\ell(u)\ell(v)} < \delta t_{uv}$, $t_{\ell(u)r(v)} < \delta t_{uv}$ and $t_{r(u)\ell(v)} < \delta t_{uv}$.

If the recursive call in line 6 is triggered, then $(x_{i+1}, y_{i+1}) = (r(u), v)$, and

$$t_{i+1} \geq (1 - 2\delta)t_i, \quad (17)$$

because $t_{\ell(u)\ell(v)} < \delta t_{uv}$ and $t_{\ell(u)r(v)} < \delta t_{uv}$.

Similarly, if the recursive call in line 7 is triggered, then $(x_{i+1}, y_{i+1}) = (u, r(v))$, and (17) holds because $t_{\ell(u)\ell(v)} < \delta t_{uv}$ and $t_{r(u)\ell(v)} < \delta t_{uv}$.

Along the chosen path in $\mathcal{T}$, suppose that line 3 is executed a times, line 4 is executed b times, line 5 is executed c times, line 6 is executed d times, and line 7 is executed e times. In each of the recursive calls, the height of one of the trees decreases by 1. Therefore, $a + b + c + d + e \leq 2m$. Consequently, we have

$$\begin{aligned} t_{uv} &\geq t_0 \delta^{a+b} (1 - 3\delta)^c (1 - 2\delta)^{d+e} \\ &> 2^m \delta^{a+b} (1 - 3\delta)^{c+d+e} \\ &\geq 2^m \delta^{a+b} (1 - 3\delta)^{2m-a-b} \\ &= 2^m \left(\frac{\delta}{1 - 3\delta} \right)^{a+b} (1 - 3\delta)^{2m} \end{aligned} \quad (18)$$

Since (x_k, y_k) is a leaf of $\mathcal{T}$, we must have $t_k = 1$. Hence the right-hand-side of (18) must be less than 1, which implies, for the choice of β , that $a + b > \beta m$. Now, a positive δ less than $\frac{1}{3} - \frac{1}{3\sqrt{2}}$ guarantees that β is positive.

We have shown that each root-to-leaf path in $\mathcal{T}$ branches at least $a + b \geq \beta m$ times, which further implies that there must be at least $2^{\beta m}$ leaves in $\mathcal{T}$. Hence T_1 and T_2 must have a common subtree on at least $2^{\beta m}$ leaves. $\square$

Remark 18. Observe that in the above analysis, we showed that each root-to-leaf path in $\mathcal{T}$ has length at least βm , which implies that it is possible to find an agreement subtree with at least $2^{\beta m}$ leaves that is also balanced (and of height at least βm). One of the implications of this observation, which we state without proof, is that Lemma 16 together with algorithm **Match2** may be used to obtain a lower bound of $2^{\gamma m}$ for an agreement subtree of more than 2 balanced binary trees of height m for a sufficiently small positive γ . For example, we call algorithm **Match2** for two rooted, balanced trees T_1 and T_2 , obtaining a rooted, balanced agreement subtree, say T_{12} , and then call algorithm **Match2** for T_{12} and T_3 , obtaining a rooted, balanced agreement subtree T_{123} , and so on.

Theorem 19. *There exists a constant $c > 0$ such that, if T_1 and T_2 are balanced, binary trees on the same leaf-set, both in $\mathcal{B}_m$ or both in $\mathcal{C}_m$, then they have a maximum agreement subtree on at least $2^{\beta m - c}$ leaves.*

Proof. As in Theorem 8, we consider the two cases: the trees are either both in class $\mathcal{B}_m$ or both in class $\mathcal{C}_m$. When the trees are both in class $\mathcal{B}_m$, the proof is analogous to the corresponding case in Theorem 8, except that it invokes Corollary 17 instead of Lemma 3.

When the trees are in class $\mathcal{C}_m$, the analysis differs only slightly from that in Theorem 8. We delete one of the branches of T_1 rooted at the center, and root the resulting tree at the center (which now has degree 2). Let X be the leaf-set of the pruned tree. We cannot simply take a restriction of T_2 to the leaf-set X as in Theorem 8, since $T_2|X$ may not be a balanced tree. We instead delete one of the branches of T_2 rooted at its center, and root the pruned tree at its center. Let Y be the leaf-set of the pruned tree. Now we can ensure that $|X \cap Y| \geq 2^{m+1}/3$ by appropriately choosing the branches of T_1 and T_2 to be deleted. We apply **Match2** to the rooted trees $T_1|X$ and $T_2|Y$. The analysis of **Match2** does not change, except that we now have a constant factor $2/3$ on the right-hand-side of (18). Therefore, with a, b, c, d, e defined as in the alternative proof of Corollary 17, we have

$$a + b > m \left(\frac{1 + 2 \log(1 - 3\delta) - (1/m) \log(3/2)}{\log(1 - 3\delta) - \log \delta} \right).$$

Taking $c = (\log 3 - 1)/(\log(1 - 3\delta) - \log \delta)$, there are at least $2^{\beta m - c}$ leaves in a common subtree. $\square$

In fact, we have a similar result when the two trees are “almost balanced”.

Proposition 20. *For every $k > 0$, there is a constant $\beta_k > 0$ such that, if T_1 and T_2 are binary trees on a leaf-set of cardinality n , each of radius at most $k \log n$, then they have a maximum agreement subtree on at least n^{β_k} leaves.*

Proof. The proof is analogous to the alternative proof of Corollary 17: the only change is that now we have $a + b + c + d + e \leq 2k \log n$. We use a value of $\delta > 0$ such that

$$\beta_k := \frac{1 + 2k \log(1 - 3\delta)}{\log(1 - 3\delta) - \log \delta}$$

is positive, and we have $a + b \geq \beta_k \log n$. $\square$

Concerning the maximum agreement subtree problem for balanced trees, we believe in the following.

Conjecture 21. *Any two balanced, rooted, binary trees of height m have an agreement subtree on at least $2^{m/2}$ leaves.*

We now describe an example of a pair of rooted, balanced, binary trees of height $2k$, for each $k > 0$, which we believe is an extremal example. Let T_1 and T_2 be balanced, binary trees of height $2k$, rooted at u and v , respectively, and both drawn top-down. Let the leaves of T_1 be labelled $1, 2, \dots, 2^{2k}$ from left to right. We label the leaves of T_2 from left to right according to the sequence $\text{swap}(1, 2, \dots, 2^{2k})$, which we define recursively as follows:

1. If S is a sequence of length 1, then

$$\text{swap}(S) = S.$$

2. If S is a sequence of length 4^i , with $i > 0$, written as $S := S_1 : S_2 : S_3 : S_4$ as a concatenation of 4 sequences of length 4^{i-1} each, then

$$\text{swap}(S) := \text{swap}(S_1) : \text{swap}(S_3) : \text{swap}(S_2) : \text{swap}(S_4).$$

Proposition 22. *Trees T_1 and T_2 have no rooted agreement subtree with more than 2^k leaves.*

Proof. We prove the result by induction on k . When $k = 1$, the trees have 4 leaves, with the leaves of T_1 labelled 1, 2, 3, 4 from left to right, while the leaves of T_2 labelled 1, 3, 2, 4 from left to right. In this case, a rooted agreement subtree cannot have more than 2 leaves.

In the general case, the inductive argument goes as follows. Let u_1 and u_2 be the children of $\ell(u)$, and let u_3 and u_4 be the children of $r(u)$. Similarly, in T_2 , we label the grandchildren of v by v_1, v_2, v_3, v_4 . By construction, we have $L(T_1^{(u_1)}) = L(T_2^{(v_1)})$, $L(T_1^{(u_2)}) = L(T_2^{(v_3)})$, $L(T_1^{(u_3)}) = L(T_2^{(v_2)})$, and $L(T_1^{(u_4)}) = L(T_2^{(v_4)})$. But a rooted balanced agreement subtree cannot have leaves from more than two of the sets $L(T_1^{(u_i)})$, $i \in \{1, 2, 3, 4\}$. Therefore, $\text{mast}\{T_1, T_2\} \leq 2 \times \text{mast}\{T_1^{(u_1)}, T_2^{(v_1)}\} \leq 2 \times 2^{k-1} = 2^k$. $\square$

An analogous but slightly weaker statement holds for unrooted trees. We use the same labelling scheme as in the rooted case, but remove the roots, i.e., we delete the vertex u , and the edges $\{u, \ell(u)\}$ and $\{u, r(u)\}$, and add an edge $\{\ell(u), r(u)\}$, and similarly make T_2 unrooted.

Proposition 23. *Trees T_1 and T_2 have no agreement subtree with more than $3 \times 2^{k-1}$ leaves.*

Proof. We prove the result by induction on k . When $k = 1$, the trees have an agreement subtree on 3 leaves, but not 4. In the general case, as in the rooted case, $L(T_1^{(u_1)}) = L(T_2^{(v_1)})$, $L(T_1^{(u_2)}) = L(T_2^{(v_2)})$, $L(T_1^{(u_3)}) = L(T_2^{(v_3)})$, and $L(T_1^{(u_4)}) = L(T_2^{(v_4)})$. For $i \in \{1, 2, 3, 4\}$, let A_i denote the set of leaves from $L(T_1^{(u_i)})$ that are in a maximum agreement subtree R . But an agreement subtree cannot have leaves from all four sets $L(T_1^{(u_i)})$, $i \in \{1, 2, 3, 4\}$. Therefore, $A_i = \emptyset$ for some $i \in \{1, 2, 3, 4\}$.

Case 1: Two or three of the four sets A_i are non-empty. Without loss of generality, let A_1 and A_2 (and possibly also A_3) be non-empty. For $i \in \{1, 2, 3\}$, let x_i be the most recent common ancestor of leaves in A_i in the rooted subtree $T_1^{(u_i)}$. Now we observe that $R|_{A_1}$ rooted at x_1 is a rooted agreement subtree of $T_1^{(u_1)}$ and $T_1^{(v_1)}$, and $R|_{A_2}$ rooted at x_2 is a rooted agreement subtree of $T_1^{(u_2)}$ and $T_1^{(v_2)}$, and, if A_3 is non-empty, $R|_{A_3}$ rooted at x_3 is a rooted agreement subtree of $T_1^{(u_3)}$ and $T_1^{(v_3)}$. Therefore, $|L(R)| = |A_1 \cup A_2 \cup A_3| \leq 3 \times 2^{k-1}$ (by Proposition 22).

Case 2: A maximum agreement subtree R has leaves from only one of the four sets $L(T_1^{(u_i)})$, $i \in \{1, 2, 3, 4\}$. Without loss of generality, let $L(R) \subseteq L(T_1^{(u_1)})$. In this case, by induction, $\text{mast}\{T_1, T_2\} \leq 3 \times 2^{k-2} < 3 \times 2^{k-1}$. $\square$

We end by presenting another proof of the rooted case with a different labelling scheme. Since T_1 and T_2 have height $2k$, each node at depth k in these trees is the root of a balanced tree of height k (they are in the middle level). Let the nodes at depth k in T_1 be called $u_1, u_2, \dots, u_{2^k}$. Similarly, let $v_1, v_2, \dots, v_{2^k}$ be the nodes at depth k in T_2 . Consider a $2^k \times 2^k$ matrix A with its entries being precisely the elements of $\{1, 2, \dots, 2^{2k}\}$ without repetition, placed arbitrarily. For each $i \in \{1, 2, \dots, 2^k\}$, let the leaves of $T_1^{(u_i)}$ be labelled with entries in the i -th row of A . Similarly, let the leaves of $T_2^{(v_j)}$ be labelled with entries in the j -th column of A . Hence, we have

$$|L(T_1^{(u_i)}) \cap L(T_2^{(v_j)})| = 1 \quad (19)$$

for all $i, j \in \{1, 2, \dots, 2^k\}$.

Alternative proof of Proposition 22. Assume, for the purpose of contradiction, that there exists $S \preceq T_1, T_2$ with more than 2^k leaves. Let f_1 and f_2 be maps that realize $S \preceq T_1$ and $S \preceq T_2$, respectively. Note that

$$\text{depth}_S(x) \leq \text{depth}_{T_i}(f_i(x)) \quad (20)$$

for any $x \in V(S)$, and $i = 1, 2$. By the assumption on S , there must be an internal node w of S of depth at least k . Hence, by (20), we have $f_1(w) \in V(T_1^{(u_i)})$ for some i , and $f_2(w) \in V(T_2^{(v_j)})$ for some j . But S^w has at least two leaves, which must be simultaneously in $L(T_1^{(u_i)})$ and $L(T_2^{(v_j)})$. This contradicts (19). The proposition follows. $\square$
